Earlier this year, people from nearly every corner of the world descended upon Iceland to catch a glimpse of the Northern Lights, otherwise known as aurora borealis, in all their glory. This year, several of those same people were treated to a new spectacle: three stunning double rainbow formations. Double rainbows, like the ones we see in movies, are a rarity. An entire rainbow is a result of reflection -- light refracting through raindrops off of a surface and back into the sky. A rainbow with two sets of colors was first discovered in the late 19th century by British scientist Oliver Lodge (who, in honor of his discovery, got to name it after himself). Lodge's findings sparked a flurry of interest among scientists and photographers, and since then, double rainbows have been discovered more and more frequently. But, according to digital image processing company Lytro, double rainbows are still relatively rare: It says that most rainbows on Earth have a maximum of seven colors. The two rainbows observed in Iceland this year were captured by photographer Dagn3, Elsa3sdottir. In total, she captured about 20 frames of the rare event. While it's impossible to say exactly where and when these two rainbows appeared, one was photographed in the town of Reykjav3k on the night of May 12th and the other in the town of Akureyri on May 14th. Check out two of the best photos of the double rainbows below: Double Rainbow in Reykjav3k, Iceland, on May 12, 2018 Flickr user Dagn3, Elsa3sdottir Double Rainbow in Akureyri, Iceland, on May 14, 2018 Flickr user Dagn3, Elsa3sdottirThe development of reversible biocompatible collagenous vascular prostheses. Synthetic polymers have been widely used to mimic the complex mechanical, biochemical, and physiologic properties of tissue. However, synthetic biomaterials have poor ability to remodel and form neo-tissue at the host-material interface. In the current work, in vivo experiments were performed using c6a93da74d
